L13 – Clustering and Mixture
Models

Clustering

Unsupervised classification

Central problem is defining a cluster

Parametric: use a cluster criterion, either a “distance” or “distortion function” (does not have to be a mathematical metric) for closeness to a model of the distribution

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu_assist_pro

Model-based clustering produce representative values of the data in the cluster. For example, the centroid. Representative values are substitutes for the data in lossy data compression (e.g. scalar and vector quantization). Hence clustering and lossy coding are related.

Model-Based Clustering

General algorithm properties

Data – x_1, x_2, \dots, x_N each to be assigned to one of L clusters or classes $\omega_1, \dots, \omega_L$

Assignment of the i th data point to a cluster is denoted

$$\omega_{k_i}, k_i \in \{1, \dots, L\}$$

<https://eduassistpro.github.io/>

Classification of entire dataset is den

$$\Omega = \{ \omega_{k_1}, \omega_{k_2}, \dots, \omega_{k_N} \}$$

Add WeChat edu_assist_pro

There's a cluster criterion function $J(\Omega)$

and a best clustering

$$\Omega^* = \arg \min_{\Omega} J(\Omega)$$

Model-Based Clustering

General Properties (cont'd)

There are a set of parameters associated with the k^{th} cluster – denoted θ_k . The parameters may include the mean of the data in the cluster, the covariance of the data in the cluster, and other summary statistics.

Assignment Project Exam Help

The union of all these is Θ . <https://eduassistpro.github.io/>

The clustering criterion function is a function of the parameters

Add WeChat edu_assist_pro

$$J = J(\Theta, \Omega)$$

and the best clustering model simultaneously minimizes J over the cluster assignment and the parameters

$$(\Theta^*, \Omega^*) = \arg \min_{\Theta, \Omega}$$

Example K-means

Classic algorithm. (MacQueen. Some methods for classification and analysis of multivariate observations, in Proce. 5th Berkeley Symposium on Mathematical Stat. and Prob., vol 3, 1967.)

Criterion function is the average squared distance between the data and the cluster “means”

$$J = \sum_{i=1}^I \frac{N_i}{N} \frac{1}{N_i} \sum_{j=1}^{N_i} \|x_j^{(i)} - m_i\|^2$$

where $x_j^{(i)}$ is the j^{th} data point in cluster i , and N_i is the number of data points assigned to cluster i .

The m_i are the “means” associated with the clusters – collectively they comprise the parameters Θ associated with the clusters. (We have yet to show that these are statistical means, hence the quotation marks.)

Note that $\frac{N_i}{N}$ is the fraction of data points in the i^{th} cluster. It's an estimator of the cluster prior P_i .

K-Means Iterative Optimization

- Freeze the means m_i , and find the assignment Ω that minimizes J . This assigns x_j to the cluster whose mean m_r is the closest in Euclidean distance to x_j .

$$\|x_j - m_r\| < \|x_j - m_k\| \quad \forall k \neq r$$

- Freeze the cluster means to the centroid of each cluster

<https://eduassistpro.github.io/>

$$m_r = \frac{1}{N_r} \sum_{i=1}^{N_r} x_i^{(r)}$$

Since the cluster assignments depend on the m_k , and the means depend on the cluster assignment Θ , we must iterate these two steps.

LGB

The k-means algorithm arose in the statistics community. It was independently discovered in the EE community where it's known as the Lloyd, Gray, Buzo (LGB) algorithm used to design vector quantizers for lossy coding.

Assignment Project Exam Help

The algorithm can be formulated for the squared Euclidean distance function that is bounded below by zero

<https://eduassistpro.github.io/>

Add WeChat: edu_assist_pro

$$d(x_i, \theta_r) \geq 0$$

The criterion function is then

$$J = \sum_{i=1}^L \frac{N_i}{N} \frac{1}{N_i} \sum_{j=1}^{N_i} d(x_j, \theta_i)$$

LBG Optimization

As before the optimization is iterative and proceeds in two steps

- Freeze the cluster parameters θ_k and assign each datapoint x_i to the cluster with lowest distortion

$$x_i \in \omega_r \text{ where } d(x_i, \theta_r) < d(x_i, \theta_j), \quad \forall j \neq r$$

<https://eduassistpro.github.io/>

- Freeze the clusters and optimize the parameters to minimize the distortion in each cluster. The resulting values of the parameters θ_k are called the *generalized centroids*, they depend on the distortion function (may not be actual centroid)

$$\theta_r = \arg \min_{\theta} \frac{1}{N_r} \sum_{i=1}^{N_r} d(x_i^{(r)}, \theta)$$

LBG Convergence

Each of the two optimization operations either lowers J , or leaves it unchanged. Since J is bounded below, the algorithm converges to a (local) minimum of J .

For a finite number of data points, J stops changing after a finite number of steps. For L clusters and N datapoints, there are L^N different assignments, to get to a local minimum of J in L^N steps. Each such assignment, together with a set of parameters Θ^* produces a local minimum of J . The algorithm must arrive at a local minimum of J in L^N steps.

Note – the convergence means J comes to rest at a local minimum. It's conceivable that Ω may continue to change (a finite number of times).

K-means Boundaries

For Euclidean distance distortion, boundaries between clusters are piecewise linear and bisectors perpendicular to the line segment between pairs of means. A point x on the boundary between clusters r and s must satisfy

$$\|x - m_r\|^2 = \|x - m_s\|^2$$

expanding the quad <https://eduassistpro.github.io/>

$$2 x^T (m_r - m_s) + (m_r + m_s)^T (m_r + m_s) = 0$$

which is linear in x . (You can prove the bisector property yourself.)

The set of boundaries is called a Voronoi tessellation.

K-means Partition and Mean Location

The algorithm tends to concentrate the means where $p(x)$ is high.

Assignment Project Exam Help

2-D Gaussian data (blue dots) and 30 means (red circles) placed by k-means, iterating 65 times over a dataset of 1000 points.

<https://eduassistpro.github.io/>

Add WeChat edu_assist_pro

Relation to Gaussian Mixture Models

Take a Gaussian mixture model with spherical components all with the same variance. Don't fit the component variance, but instead regard it as a 'knob'. The model is

Assignment Project Exam Help
<https://eduassistpro.github.io/>

$$p(x) = \sum_{i=1}^L P_i p(x|i), \quad p(x|i) = \frac{1}{\sqrt{(2\pi)^n \sigma^2}} \exp\left(-\frac{1}{2\sigma^2} |x - m_i|^2\right)$$

Add WeChat edu_assist_pro

the posterior cluster probabilities are

$$p(i|x) = \frac{P_i p(x|i)}{\sum_j P_j p(x|j)} = \frac{1}{1 + \sum_{j \neq i} \frac{P_j p(x|j)}{P_i p(x|i)}}$$

K-means and Gaussian Mixtures

We have the cluster posteriors

$$p(i | x) = \frac{P_i p(x | i)}{\sum_j P_j p(x | j)} = \frac{1}{1 + \sum_{j \neq i} \frac{P_j p(x | j)}{P_i p(x | i)}}$$

with

$$\frac{P_j p(x | j)}{P_i p(x | i)} = \frac{P_j}{P_i} \exp \left(-\frac{1}{2\sigma^2} (|x - m_j|^2 - |x - m_i|^2) \right)$$

K-means and Gaussian Mixtures

Take the limit $\sigma^2 \rightarrow 0$. It's quick to show that, provided non of the priors P_i are zero,

$$\lim_{\sigma^2 \rightarrow 0} p(i|x) = \begin{cases} 1 & \text{if } |m_i - x| < |m_k - x| \quad \forall k \neq i \\ 0 & \text{otherwise} \end{cases}$$

<https://eduassistpro.github.io/>

So the cluster posteriors become cluster assignments (0 or 1) with the same cluster assignments in k-means!

K-means and Gaussian Mixtures

The optimal position of the mean for the i^{th} cluster is (recall the EM algorithm for mixture model fitting)

N

$$m_i = \frac{1}{N_i} \sum_{l=1}^{N_i} x_l^{(i)}$$

Assignment Project Exam Help

with our limiting values of the posteriors,

<https://eduassistpro.github.io/>

$$\lim_{\sigma \rightarrow 0} \pi_i = \frac{1}{N_i} \sum_{l=1}^{N_i} x_l^{(i)}$$

Add WeChat: edu_assist_pro

So the M-step of the EM algorithm becomes the cluster mean adjustment step of the k-means algorithm.

Thus, the EM algorithm for fitting spherical Gaussian mixture models reduces to the k-means clustering algorithm in the limit that the component variances are kept the same and taken to zero.
